INTRODUCTION

Caveat emptor

What do we call trade communities?

This is a work in progress. We are still in the garden of forking paths.

I would not mind impressing you, but more realistically I am here to share and learn.

Trade blocs, trade regions… groups of countries that trade more with one another than with the rest of the world according to some metric

Trade communities play a role in world trade

Gopinath et al. (2025), Bonadio et al. (2026), Anderson and Norheim (1993)

https://doi.org/10.1016/j.jinteco.2024.104042 ; Gopinath, Gita, et al. "Changing global linkages: A new Cold War?." Journal of International Economics 153 (2025): 104042.

https://doi.org/10.1016/j.jinteco.2025.104204 ; Bonadio, Barthélémy, et al. "Playing with blocs: Quantifying decoupling." Journal of International Economics (2026): 104204.

Current rising international tensions have increased the interest for securing supply chains through trade fragmentation by geopolitical lines. Studies show the rise of friend-shoring, near-shoring and decoupling by trading more with geopolitical friends.

This is probably bad for global trade. It does not need to be so. Anderson and Norheim in an old paper (1993) even show that generally, regionalisation and globalisation are positively correlated. And the story of "hyperglobalisation" from the 1980s to the 2000s, around the rise of the European Union, NAFTA, and Factory Asia can lead to a positive view of the formation of trade blocs. The 1930s, with decoupling between trade blocs organised around formal and informal empires, gives less reason for optimism.

Bhagwati-style “building blocs or stumbling blocs”

We look at this phenomenon, with historical depth, which allows to show if the current period is unusual.

We look for trade communities with network science

Fagiolo et al. (2010) De Benedictis & Tajoli (2011), Piccardi & Tajoli (2012), Iapadre & Tajoli (2014)

We do not pre-impose trade blocs

It is not only that countries trade with friends. It is also that you want to become friends with the countries you trade with. So trade communities arising from the ground are interesting to study.

Blocs might arise from reasons that are not linked to geopolitical tensions, and the contrast between different periods is interesting.

In the early 1990s, it was not obvious with whom Eastern Europe would trade more. You could argue that trade created the community rather than the reverse.

Trade communities have economic consequences.

Lesger (2006), Miller (2012), Rauch (1999, 2001), Rauch & Trindade (2002), Combes, Lafourcade & Mayer (2005), Chaney (2014)

But then you have an issue. The creation of trade communities is important because it has consequences for trade. It might encourage more trade, but of course that relationship is deeply endogenous to the creation of communities.

Except for the extensive margin.

Look at the story of Amsterdam in the 16th and 17th centuries (Lesger 2006). From an actual entrepôt for goods to an information entrepôt that encouraged the formation of direct links between the Baltic and Western Europe for naval stores, grain, and various raw materials.

We argue this happened because of the creation of trade communities of people.

Ethnic work, eg. Greif's work on the Maghribi traders of the 10th-11th century

Double entendre

European expansion created intercontinental networks of business and administrative people that encouraged the formation of trade

Shared business and financial networks give access to shared information through intermediaries.

What are the composition, determinants and effects of trade communities over two centuries ?

Outline

1. Data
2. Identifying trade communities
3. Finding the determinants of trade communities
4. Finding the effect of trade communities

I. DATA

DATA (1)

Besides well known IMF data from 1948

A database of bilateral world trade 1833-1938

RICardo project since 2004. 690,000 trade flows

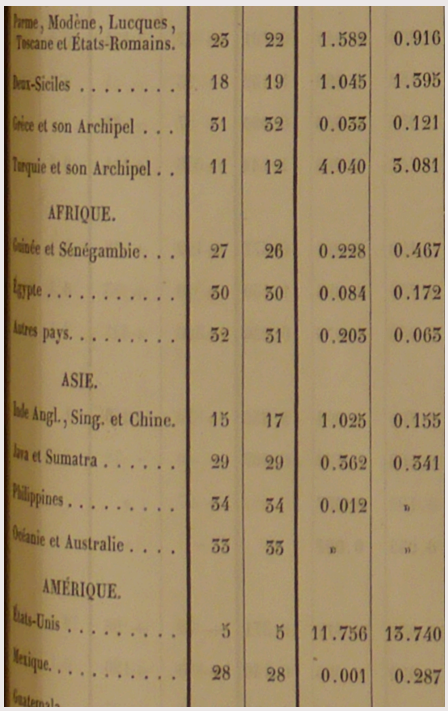

https://ricardo.medialab.sciences-po.fr/

Girard, Paul, et al. « **RICardo Project : Exploring XIX Century International Trade** ». *Digital Humanities 2016: Conference Abstracts* [Agiellonian University & Pedagogical University, Kraków, Poland], 2016, p. 208-10, http://dh2016.adho.org/abstracts/177.

All started with the discovery of the "Annales du Commerce Extérieur", an annual French source from the 1830s that reported bilateral trade statistics from numerous foreign countries

About
FR | EN
The RICardo Project
Trade between Nations from c. 1800 to 1938
RICardo (Research on International Commerce) is a project dedicated to trade between nations over a period spanning the beginning of the Industrial Revolution to the eve of the Second World War.
It combines a historical trade database covering all of the world's countries and a website which invites to an exploration of the history of international trade through data visualizations.

GeoPolHist: Italy (325)

Open the GeoPolHist page for Italy

For each entity, we list their political status along with time and their links to sovereign parent entities.

DATA (8)

To build coherent bilateral trade matrices, one needs to reduce trading entities heterogeneity thanks to GeoPolHist data

1. identify non-polities, groups… informal entities.
2. aggregate non-polities entities (localities, part-of…) to their polities.
3. split trade of groups, geographical and colonial areas

DATA (9)

Method: Multilayer networks combining trade and politics

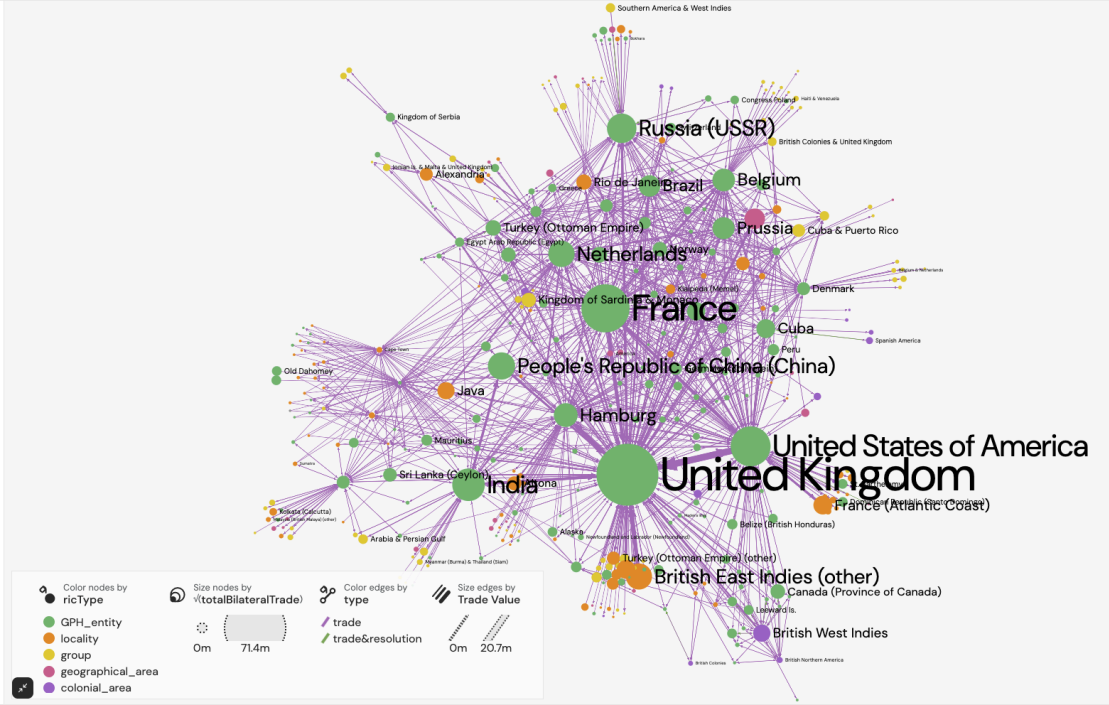

Build yearly networks that combine:

trade flow edges from **RICardo** dataset

geopolitical resolutions edges mainly from **GeoPolHist** dataset (« localities » , eg Bilabo, come from **RICardo**)

Our proposal is to merge those two dataset RICardo for trade, GeoPolHist into one multilayer network.

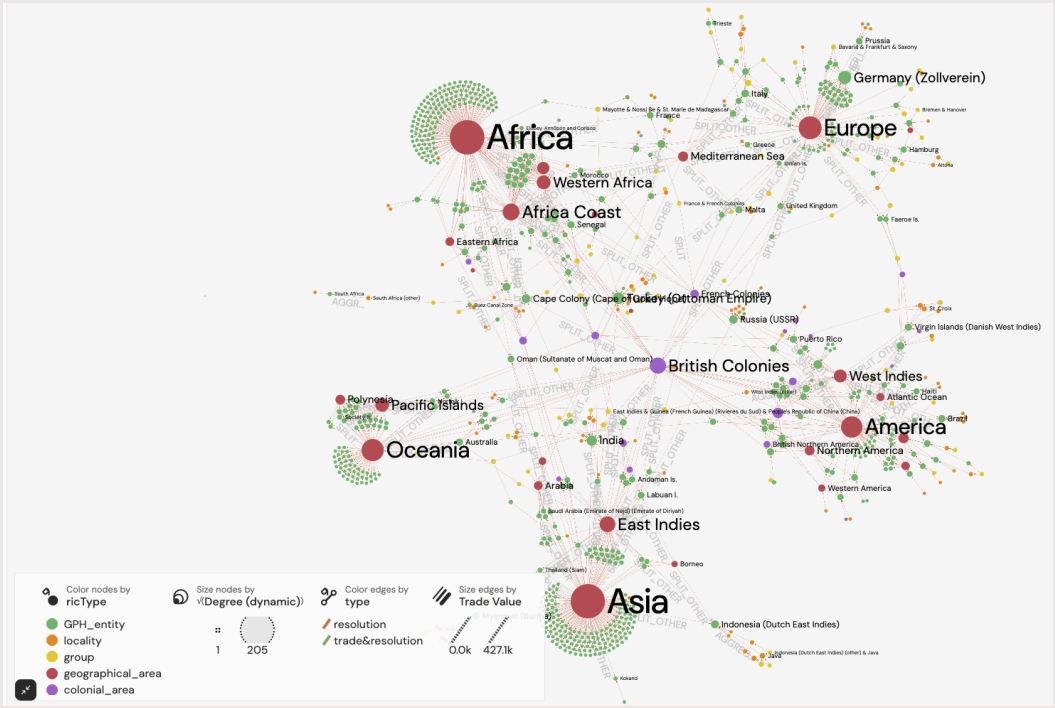

The 1850 trade network

mention Gephi lite

DATA (10)
Harmonization process

1. Polities resolution
2. Trade reporters aggregation/split
3. Trade partners aggregation
4. Trade partners splits with year ratio method
5. Trade reporters & partners splits with gravity model method

Bilateral trade data model

===/assets/trade data model.png

size: contain

Note that we have trade between reporters but also between reporter and partners, i.e. entity citing in sources but for which we don't have extensive source

Add Geopolitical resolution edges

From RICardo:

cypher

(Locality)-[:AGGREGATE_INTO]->(parent entity)

(Group)-[:SPLIT_INTO]->(members)

From additional data edited for this paper:

cypher

(Geographical Area)-[:SPLIT_INTO]->(members)

(Informal)-[:SPLIT_INTO]->(members)

From GeoPolHist:

cypher

(`Part of` GPH entity)-[:AGGREGATE_INTO]->(sovereign)

(Colonial Area)-[:SPLIT_INTO]->(colonies)

For colonial area we combine geographical area data table with GPH data.

===/assets/multilayer_data_model_1.png

size: contain

===/assets/multilayer_data_model_2.png

size: contain

===/assets/multilayer_data_model_3.ain

Polity resolution

For each non-polity entity (source: GPH + Ricardo localities), we traverse resolution edges until finding an polity.

This method allows to traverse multiple non-polity entities until finding the good one like a group containing a part of:

cypher

(D)<-[:SPLIT]-(D & part of A)-[:SPLIT]->(part of A)-[:AGGREGATE_INTO]->(A)

Polities of **D & part of A** are **D** and **A**.

Trade reporters aggregation/split

Reporters needs to be treated before the partners as areas desagregations needs a stable reporter scope.

Moreover we need to treat cases of reporters overlaps. It happens that a set of reporters report part of the same trade from different perspectives.

PS: we don't split reporters trade at this step, we prepare the work for the gravity model

Trade partner aggregation

Simple task: sum the trade figure to build the new trade edge.

PS #1: do not overwrite an existing reported trade flow
PS #2: do not create internal trade flows, discard trade flows between part of and its parent

TRADE PARTNER SPLITS WITH YEAR RATIO METHOD

Difficult task: how to decide the ratios to split one trade value into many?

We look into **adjacent years** (+/- 10-years window) networks

TRADE PARTNER/REPORTER SPLITS WITH GRAVITY MODEL METHOD

We try to impute flows we couldn't split with the adjacent years method by using a ppml gravity model (Anderson et Van Wincoop (2003), Santos Silva & Tenreyro (2006)).

We do this cross-section. Very far from a balanced panel

23

for *dissociated* trade flows with the **same set of partners** for the same reporter.

If we find one compatible year, we calculate **split ratios** for that year and reapply those **on the original trade value**.

This process support partial split.
If a set of partners from a group is found as one + another group, the one found will be split, the rest will stay as a group.

Special cases: Areas

Areas (geographical or colonial) are implicit groups.

The composition of the group is not explicit in the source.

We use geographical or colonial sets which we adapt to the source context:

we remove all theoretical members of the area which are already cited by the reporter

we remove those that would not be part of the trade network otherwise (not directly cited by another source)

We use fixed effects on importer and exporters, geographical distance, geopolitical link existence (GeoPolHist) variables (to be extended).

The inferred values are used to compute a ratio which is then applied on the original values.

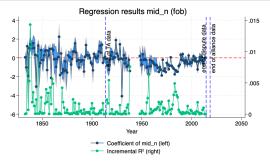

Anderson, James E., et Eric Van Wincoop. « Gravity with Gravitas: A Solution to the Border Puzzle ». *American Economic Review*, vol. 93, no 1, February 2003, p. 170-92. DOI.org (Crossref), https://doi.org/10.1257/000282803321455214.

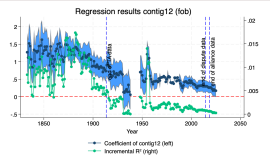

DATA (11)

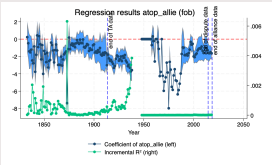

Control variables

How much trade do we normalise? Value

How much trade do we normalise? Flows

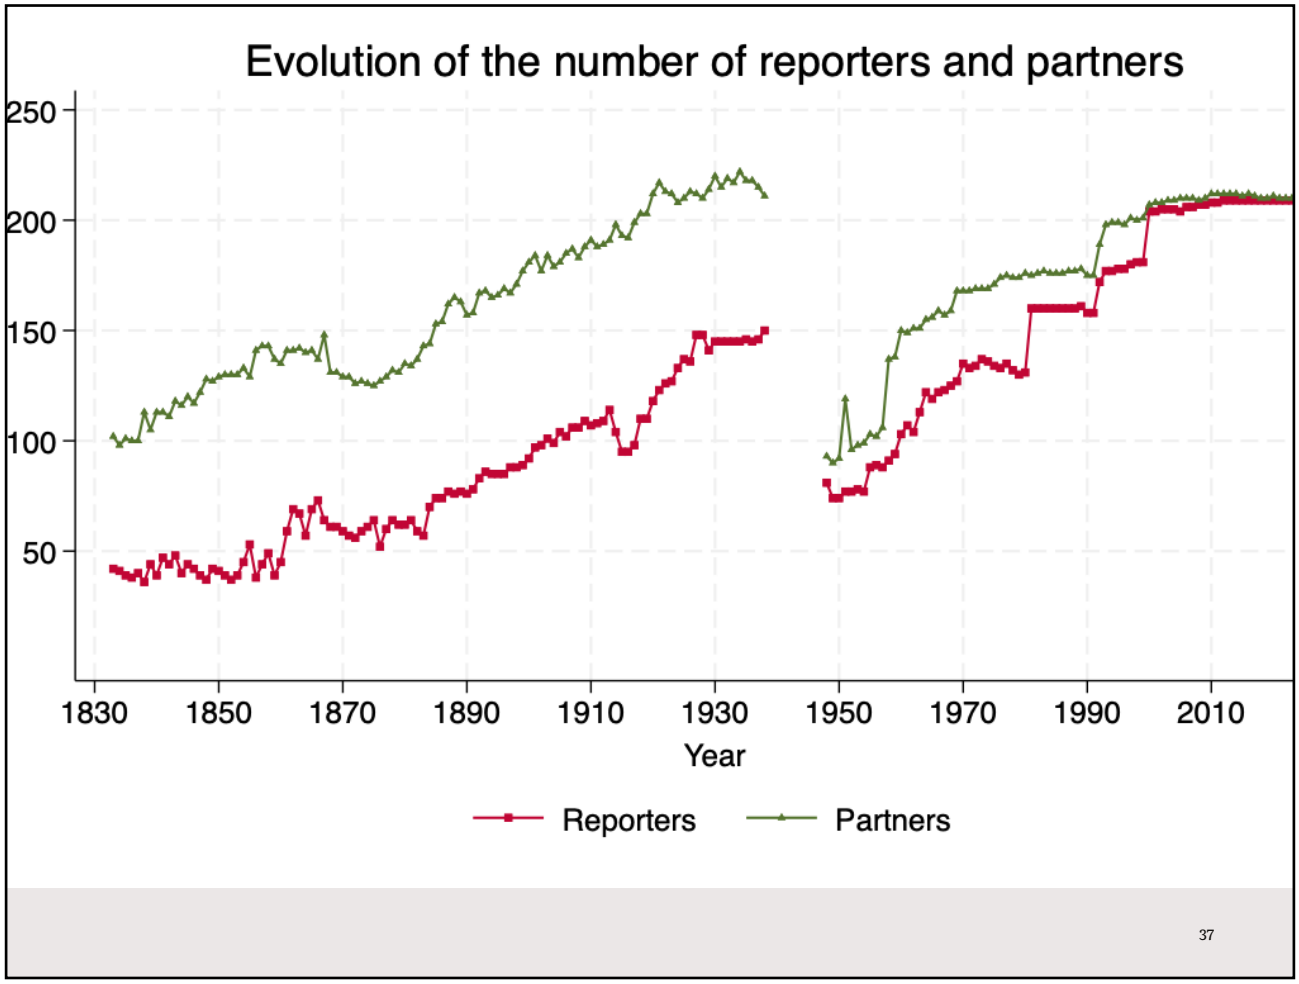

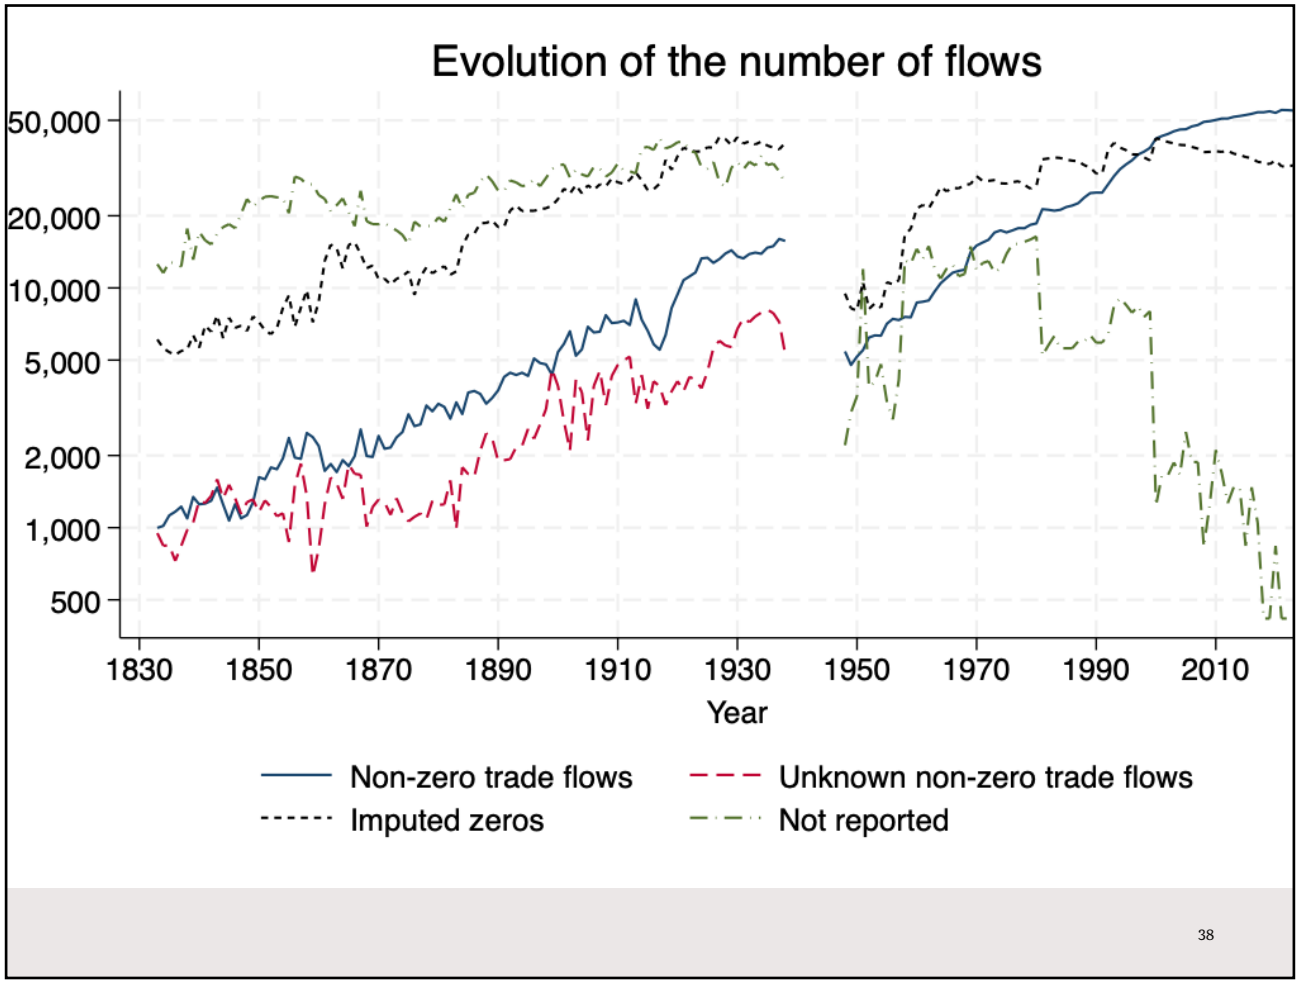

36

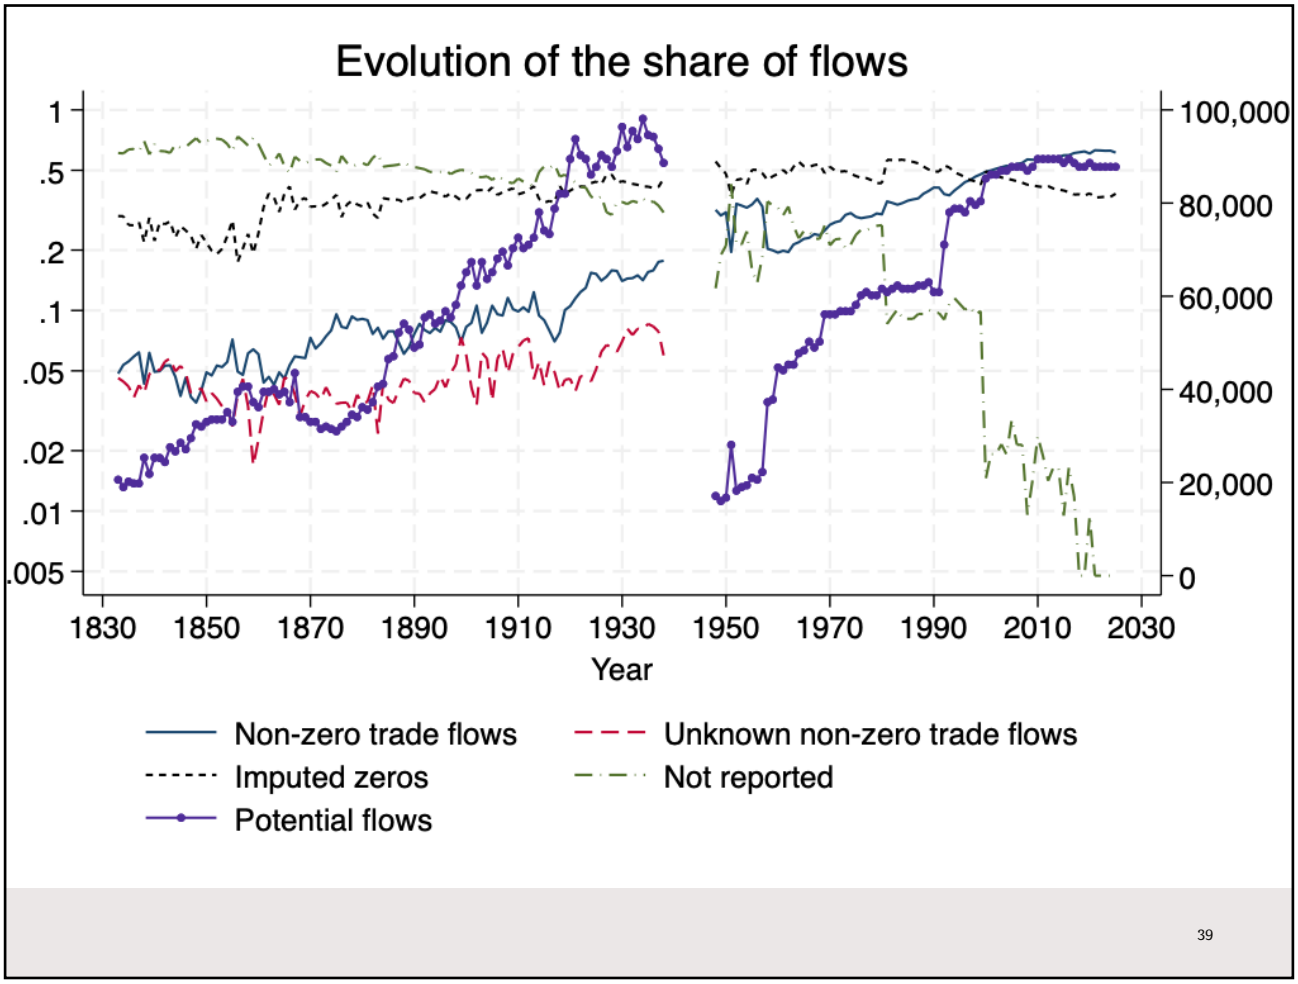

Keep it mind that we are working with the fringe of the trade networks, ou problematic flows are numerous but with smaller values on average

For the study of the extensive margin, flows are very important

The effect on the number of trade flows is much larger than on the value of trade flows

II. IDENTIFYING TRADE COMMUNITIES

IDENTIFYING TRADE COMMUNITIES (1)

« The problem of community detection requires the partition of a network into communities of densely connected nodes, with the nodes belonging to different communities being only sparsely connected »

Trade studies: Either exogenous, or ad hoc method, such as IntraMax

Poon (1997)

Network community has worked a lot on the subject

Blondel et al. (2008) : Louvain

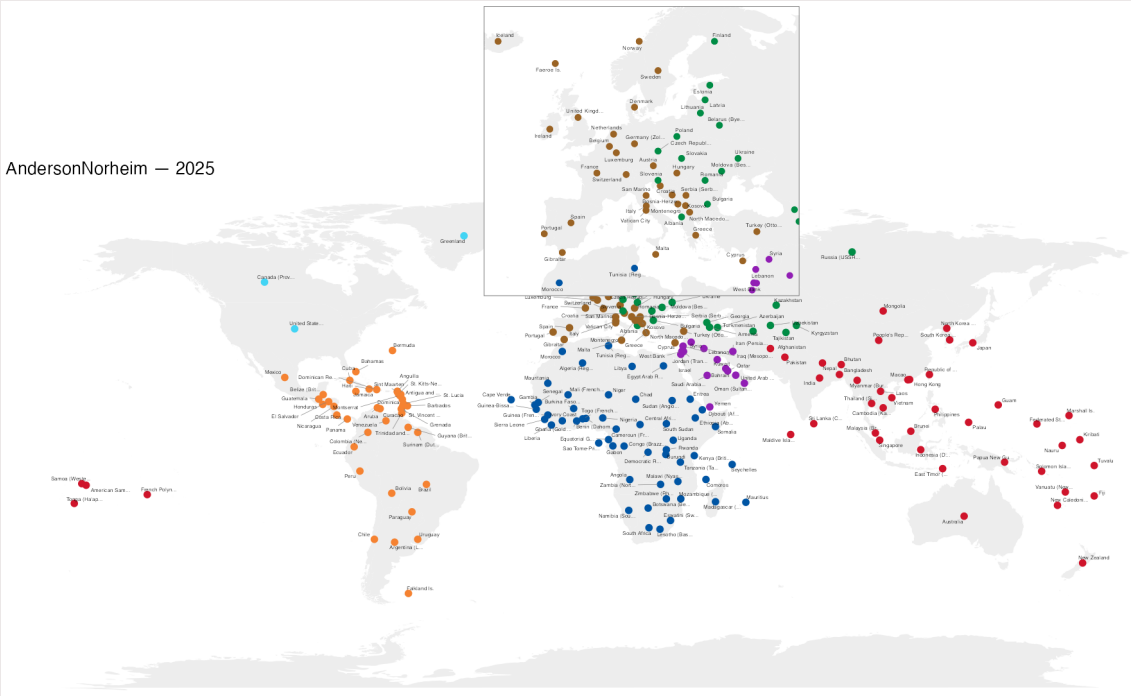

41

Poon, Jessie P. 'The Cosmopolitanization of Trade Regions: Global Trends and Implications, 1965-1990'. *Economic Geography*, vol. 73, no. 4, 1997, pp. 390–404. https://doi.org/10.2307/144560.

Anderson, Kym, and Hege Norheim. "Is world trade becoming more regionalized?." *Review of International Economics*, 1.2 (1993): 91-109.

Finger, Karl-Michael, Hege Norheim, and Kym Anderson. 1993. "Trends in the Regionalization of World Trade, 1928 to 1990." In *Regional Integration and the Global Trading System*, by Kim Anderson and Richard Blackhurst. https://www.cabidigitallibrary.org/doi/full/10.5555/19941801183.

This is the most common point of view. Anderson and Norheim. Currency blocs, political trade communities, empires...

This leads to an endogeneity issue (you might pick the composition of a bloc because you see increased inbloc trade).

It also leads to fixity over time. The relevant bloc might actually change through time, and you might miss that. Most obvious example : maybe imperial blocs are important in the 1930s and 1950s, but they loose that importance through time. And now continental blocs are important because of regional trade agreements, especially the EU.

IDENTIFYING TRADE COMMUNITIES (3)

Two issues:

1. What is the algorithm that creates the communities
2. What is the weight/proximity mesure to use?

IDENTIFYING TRADE COMMUNITIES (4) ALGORITHMS

Intramax algorithm:

1. Computes all proximities between actors/groups
2. Regroup the closest pair
3. Repeat till the regrouping increases internal trade in the group by more than 10% of world trade

Louvain algorithm:

Louvain adds a global measure grouping quality "modularity" (Newman (2006)

$$Q = \frac{1}{2m} . \sum_{i,j} \left(A_{i,j} . \frac{k_i . k_j}{2m} . \delta(c_i, c_j) \right)$$

$$Q \in [-0.5, 1]$$

Which is the ratio between the weight of links inside groups compared to random links

$A_{i,j}$ is the weight of the link (or proximity) between polities i and j that we just defined

$k_i = \sum_i A_{i,j}$ is total weight of a polity's links (it might be different from one)

$m = \frac{1}{2} . \sum_{i,j} A_{i,j}$ is the sum of all weights in the trade network divided by two

c_i and c_j are the blocs of polities i and j. The \delta$-function $\delta(u,v) is 1 if $u = v$ and 0 otherwise

M. E. J. Newman, « Modularity and community structure in networks », *Proc. Natl. Acad. Sci.* USA, vol. 103, no 23, 2006, p. 8577–8582 https://dx.doi.org/10.1073%2Fpnas.0601602103

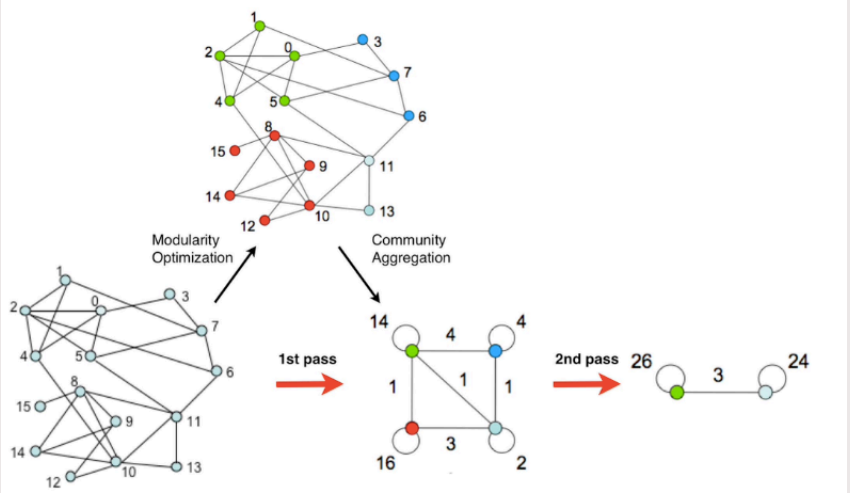

Figure 1. Visualization of the steps of our algorithm. Each pass is made of two phases: one where modularity is optimized by allowing only local changes of communities; one where the found communities are aggregated in order to build a new network of communities. The passes are repeated iteratively until no increase of modularity is possible.

Blondel et al.

45

All polities are put in their own bloc
We examine all trade partners j of a polity i and we assign i in j's bloc, where j's bloc provides the largest gain in modularity. If there are no positive gains, i stays in its bloc. Once all polities have been considered once, we examine them again in the same order and they can moved from bloc to bloc.
When all positive gain-grouping have been made, we re-create the network with the new blocs as units, considering internal trade as a self-loop. Proximity between blocs is the sum of proximity of each pair of polities. And we iterate (2 and 3) till no change in grouping is made in phase 2.
The result depends on the order in which polities are examined. We run it multiple time and aggregate the results.

Blondel, Vincent D., Jean-Loup Guillaume, Renaud Lambiotte, and Etienne Lefebvre. 2008. "Fast Unfolding of Communities in Large Networks." *Journal of Statistical Mechanics: Theory and Experiment* 2008 (10): P10008.

IDENTIFYING TRADE COMMUNITIES (5) WEIGHT/PROXIMITY

We can have up to four flows by pair.

But we cannot simply look at exports or imports because of the large number of missing observations

In all cases, we compute 1 to 4 proximities and we take the max

$$Max\left(P_{ij}^{X};P_{ji}^{X};P_{ij}^{M};P_{ji}^{M}\right)=A_{ij}=A_{ji}$$

1. We can just take raw trade

2. Intramax proximity

One looks for the polity/bloc pair that is the furthest from a random model of bilateral trade.
X_{ij} is (eg) fob exports from polity/bloc i to polity/bloc j
X'_{ij} is counterfactual, random, no friction trade, defined as:

$$X'_{ij}=\frac{X_{i.}}{X}\frac{X_{.j}}{X}X=\frac{X_{i.}X_{.j}}{X}$$

Weight/Proximity: $(X_{ij}-X'_{ij})+(X_{ji}-X'_{ji})[+(M_{ij}-M'_{ij})+(M_{ji}-M'_{ji})]$

X is world exports, Xi. is polity/bloc i's exports. X.j is exports going to polity/bloc j.

- Poon's maximisation objective is in monetary terms, and as such gives an advantage to large polity pairs.
  - We believe if a small polity does 100% of its trade with a big one, even if this trade is small in monetary terms, they must be in the same bloc. So we normalise. Kohl & Brouwer (2014)

    Proximity $= \frac{X_{ij} - X'_{ij}}{X_{i.}}, \frac{X_{ji} - X'_{ji}}{X_{j.}}, \frac{M_{ij} - M'_{ij}}{M_{.j}} and \frac{M_{ji} - M'_{ji}}{M_{.I}}$

Kohl, Tristan, and Aleid E. Brouwer. 2014. "The Development of Trade Blocs in an Era of Globalisation." *Environment and Planning A: Economy and Space* 46 (7): 1535–53. https://doi.org/10.1068/a46261.

3. TIBI (Trade Intensity Bilateral Index)

Poon's maximisation objective can also be expressed as a ratio : CEPII's Relative bilateral intensity of port Intensity:

$$X_{ij}/X'_{ij} = (X_{ij}/X_{i.})/(X_{.j}/X)) \in [-1, X/X_{.j}].$$

Inspired by Balassa (1965)'s index of comparative advantage. Eg Gaulier and Ünal-Kesenci (2004)

Iapadre (2006), Daudin et al. (2011) mention three issues:

Solving range variability

Solution: $I^1_{ij} = (X_{ij}/X_{i.})/(X_{rj}/X)) \in [0, +\infty[$

Solving range asymmetry

Solution: $I^2_{ij} = (I^1_{ij} - 1)/(I^1_{ij} + 1) \in [-1, 1]$

Solving dynamic ambiguity

Solution: $TIBI_{ij} = (I^1_{ij}/I^3_{ij} - 1)/(I^1_{ij}/I^3_{ij} + 1) \in [-1, 1]$

Where: $I^3 = (1 - (X_{ij}/X_{i.}))/(1 - (X_{rj}/X)) \in [-1, 1]$

48

CEPII's "Relative bilateral intensity of exports" Deutsch and Savage (1960), Drysdale and Garnet (1982), Freudenberg, Gaulier and Ûnal-Kensenci (1998), pp.66-68

The maximum value of the index depends on the size of $X_{.j}

The range is not symmetric around neutrality. I1 ranges from 0 to 1 if trade is less important than expected and from 1 to infinity if trade is more important than expected. To solve that issue, we use the following index, which varies between -1 and 1 and has neutrality at 0 rather than 1:

A change in the index might be in the same direction as the change in the complementary index measuring the intensity of trade between region i and all non-j regions.

Daudin, Guillaume, Christine Rifflart, and Danielle Schweisguth. 2011. "Who Produces for Whom in the World Economy?" *Canadian Journal of Economics/Revue Canadienne d'économique* 44 (4): 1403–37. https://doi.org/10.1111/j.1540-5982.2011.01679.x.

If we believe these classifications: decline of the importance of trade communities till the 1890s, stability till WWI, then increase till WWII. Decline since WWII, with not much happening since.

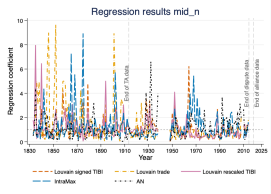

IV. DETERMINANTS OF TRADE COMMUNITIES

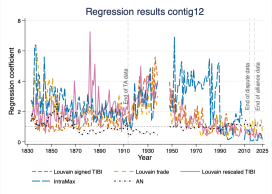

Logit regression on polity-pairs each year, with the usual control variables

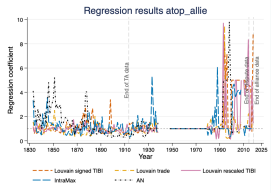

No causality, obviously

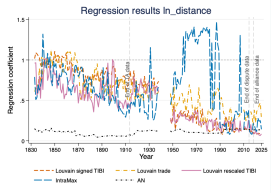

We compute the incremental R^2 (but we need a better idea)

IV. EFFECTS OF TRADE COMMUNITIES

Effects of trade communities (1)

Importance of the extensive margin (Helpman, Melitz & Rubinstein (2008), Hummels & Klenow (2005) and Felbermayr & Kohler (2006))

Basic model in the trade duration literature: Cox model with proportional hazard (Besedeš and Prusa (2006))

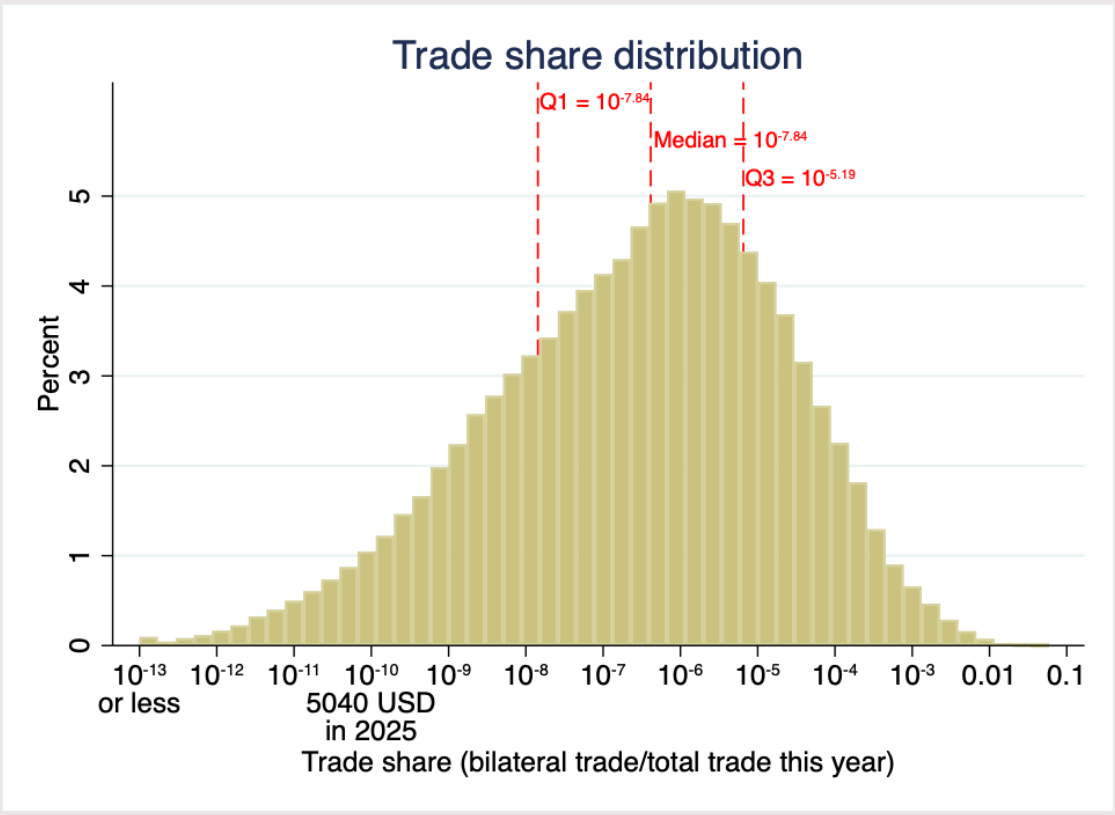

Method : cloglog. Said to be preferable to Cox model in discrete time (Hess and Persson (2012)

Or even log (weakly proportional hazards) or probit?

"Proportional hazards" means that covariates multiply a shared baseline risk by a constant factor, so the ratio of risks between any two individuals never changes over time.

Hess, Wolfgang, and Maria Persson. 2012. "The Duration of Trade Revisited: Continuous-Time versus Discrete-Time Hazards." *Empirical Economics* 43 (3): 1083–107.

82

We have an issue with the gravity model as it creates very small non-zero trade flows. So we probably want to cut off very small trade flows -- we choose one tenth of a billionth (c. 5k $ in 2025).

Same question with failed splits

TRADING FLOWS "AT RISK" (EXCLUDING SECOND AND SUBSEQUENT TRADE OBSERVATIONS)

Excluding very small flows and failed splits	Total
0	6,387,135
1	86,158
Total	6,473,293

Including very small flows and failed splits	Total
0	6,220,999
1	91,083
Total	6,312,082

Time at risk

- Duration 1 : years of directed pair existence before first trade (not counting gaps)
- Duration 2 : time since appearance (counting gaps)
- Duration 3 : time since appearance with zero (and/or very small) trade

Some pairs stay at risk a long time !

Duration dependence is mildly negative over the first three decades (hazard about 3% lower than in the first year) and turns positive for longer durations, although the latter is estimated on fewer observations.

dur3 = dur_n_fs for flag_trade_entry_n_fs

Membership in the same community raises the hazard of starting trade, by up to 33% for a pair that has always been together, but this advantage declines by about 0.9% for each additional year and disappears after about three decades

CONCLUSION

Outline

1. Data
2. Identifying trade communities
3. Finding the determinants of trade communities
4. Finding the effect of trade communities

Tentative findings

1. Chronology of the importance of trade communities
2. They are not pure artefacts

Decline of the importance of trade communities till the 1890s, stability till WWI, then increase till WWII. Decline since WWII, with not much happening since.

No sign of them being "building blocs"

They play a causal role in the formation of new trade links,

Pat on the back
Much yet to be done

92

Interdisciplinary work between history, economics and network science

More primary sources on trade statistics -- paradoxically, mainly for post-45

Improve the classification algorithm:

a) Optimise signed Louvain

b) Take ambiguity in Louvain into account
Explore non-linearity
